## **Executive Summary**

Disability and Community Care Services, Department of Communities has commissioned an evaluation of the outcomes, process and costs of the Self Directed Support pilot by a research team led by the Social Policy Research Centre (SPRC). This second report provides findings about the outcomes for participants and their families, implementation of the pilot, the process and cost analysis. It also draws together implications for future development of similar programs.

### **Background**

The Self Directed Support pilot has two key objectives: community inclusion and the empowerment of service users to make their own choices about their support (self direction). Self directed support enables individuals, their families and their other informal supporters to identify their needs, lifestyles and aspirations, and set personal goals. By giving people with disabilities access to case management and control over their allocated funding, the program allows them to be their own agents of change (Department of Communities, 2010: 7).

The Queensland Department of Communities selected two service providers from a negotiated tender process to implement the Self Directed Support pilot. One is the Sunshine Coast Children's Therapy Centre (SCCTC), which supports young children (0-6 years) with physical disabilities and their family carers and significant other informal supporters. SCCTC has one full-time services coordinator. The second is the Acquired Brain Injury Outreach Service (ABIOS) in Brisbane, which supports young adults (20-35 years) with acquired brain injury and physical disability. Existing ABIOS case managers (ten) have incorporated the self directed support function into their other responsibilities.

The two providers are funded \$240,000 per year for two years to deliver services under the pilot. The annual budget covers expenses for management, staff and operational costs; and person centred (self directed) planning and support, community inclusion, and early intervention for 40 participants per year, including self directed budgets of up to \$4000 per participant.

### **Evaluation questions**

The evaluation uses a longitudinal, mixed methods design to address three sets of research questions:

1. Participant and program outcomes: To what extent has the initiative met its objectives for individual participants?
2. Support model and service delivery processes: How effective is the model in meeting its key objectives, person centred (self directed) support, community inclusion, and early intervention?
3. Economic analysis: What are the costs and benefits of the pilot?

---

## **Outcomes for children, young people and families**

The flexibility, planning and coordination of a person's needs, a person centred service delivery approach, and empowerment are central to the successful implementation of the program. The findings show that the program is achieving its goals of improving wellbeing, independence, resilience and social participation.

*Wellbeing, independence and resilience.* Participants' physical wellbeing has improved from access to therapies and physical activity. This has improved their independence. Family members' wellbeing and resilience to cope with their circumstances has improved through reduced stress about coping with decisions about support needs, paying for support, finding information and arranging support. The wellbeing of young adults and family members is close to that of the Australian population and higher than other carers. Families report that the support is preventing them from entering a crisis and perhaps avoiding family breakdown.

*Empowerment.* Young adults have been able to make decisions and act on plans to achieve goals and steps towards goals. Family members have a better sense of control and capacity to organise, pay for and attend support services for their children.

*Social, community and economic participation.* Young children are able to participate in activities in their family, early childhood groups and school. Young adults are participating in sport, social and educational activities and paid employment. Support has enhanced families' resilience and enabled young children and their siblings to do activities together and outside the home.

*Community connections and networks.* Young adults are using mainstream community services. Families of young children are becoming familiar with community services and referral opportunities.

## **Process findings**

The program is achieving its process objectives: empowerment of service users and their families to identify their needs, set personal goals and make informed decisions about the support they need. The pilot, designed as an early intervention approach, is reaching its main target groups – children showing early signs of additional support needs, young adults with physical disability, and their families and informal supports, previously excluded or not accessing more formal support.

The goals are facilitated through strong relationships and support processes implemented by case workers; a partnership approach to planning and decision making where participants need guidance; flexibility in planning, with the option of making changes to plans as circumstances and preferences change; and consistency to the principles of the program design.

---

*Planning.* SDS planning for young children requires sensitivity, especially for families who are adjusting to understanding their child's needs. Parents want to be seen as experts of their child's support needs and to make informed decisions about how to best address these. The planning process and the provision of information empower family members and carers to take charge of their situation, and to actively seek out resources and information related to meeting their child's needs. The families are able to more effectively engage with other service providers as a result of this process.

Planning with young adults benefits from a stepped process for goal development, which provides, at its best, a supported and facilitated process of personal development for participants. Participants in the pilot felt that their plans were self-directed, and that they explicitly developed their own goals. Case workers filled in the gaps in meeting those goals, by providing pathways to move towards major goals, or suggestions and options about ways to reach goals. While participants still felt that their ideas needed to be approved before being able to be implemented, they clearly felt the program was in place for them to develop their own ideas about participation and activity.

*Funding.* Having resources to enable plans to be activated continues to be a key to the pilot for children and young adults. By the second half of the project, a few participants had chosen to manage the funding directly, although most continued to leave that responsibility with the organisation. ABIOS has actively worked to minimise the negative impact of government department finance restrictions, such as delays in payment.

*Coordinator time.* The role of the service coordinator includes planning, support, administration and partnership development. The two models in the pilot approached these roles differently, SCCTC relying on a single part-time position, and ABIOS sharing the responsibilities among case workers who also supported other programs. The single position had the strength of a consistent approach and focus. As more participants joined the program, the team approach was easier to sustain in terms of time management, integration with other resources in the organisation, peer support, quality control, partnership development and continuity of support after exit.

Opportunities for expanding the program include:

- Avoiding terminology such as 'disability' to include families who do not identify with the category;
- Extending the program beyond physical disability and six years of age, to include children with mental health disorders, learning difficulties, and challenging behaviours, up to ten years of age;
- For young adults, revising eligibility to length of time since acquiring impairment, rather than chronological age; and
- Promotional material to explain the program in a way that is attractive and understandable for young adults and families of young children.

---

## **Economic implications for program and evaluation**

The providers have operated within budget for the first 18 months of the program. They reported that they have absorbed a lot of management costs into their other operations because of the high administrative responsibilities of establishing a new program. The administrative processes to comply with financial accountability, planning processes and evaluation are a high cost to the organisations.

The self directed funding allocation has also operated within budget. The families of young children have generally spent the funds on weekly fees for therapies and related equipment. The young adults in contrast have paid for equipment or study fees to facilitate immediate access to social, community and economic activity.

The qualitative data shows that young children, their families and young adults are benefiting from case management, planning and a small budget to assist with organising the support they need to fulfil their goals. Benefits for the participants and their families are evident including wellbeing, independence and resilience; and community, social and economic participation. Initial information and contact with community services and informal networks is beginning for some families and young adults, with the support of the case workers.

---

## 1 Introduction

In 2009 the Disability and Community Care Services, Department of Communities launched the Self Directed Support – Community Inclusion Pilot (pilot). The pilot is funded through the Queensland Government’s Prevention and Early Intervention pool. A total of \$1.06 million has been allocated to implement and evaluate the pilot over two years to December 2011 (Department of Communities, 2010). The program aims to enhance independence, capacity and resilience of children and young adults with a physical disability, as well as their families and informal supporters (Section 2.1 details the program objectives).

In 2010 the Social Policy Research Centre (SPRC), University of New South Wales (UNSW) and Griffith University was contracted by the Department of Communities to evaluate the pilot from June 2010 to March 2012. The evaluation examines the outcomes, process and costs of the pilot to inform future service development. This is the second evaluation report (Baseline report see Gendera et al 2011).

### 1.1 Evaluation method

The longitudinal, mixed method evaluation design measures longitudinal outcomes for children and young adults with physical disabilities, their families and informal support; the program process; and costs. Appendix A is a summary of the evaluation and the full evaluation plan is available at Gendera et al. (2010). The following datasets were available.

#### Program data

The two service providers implementing the pilot provided quantitative program data. The longitudinal analysis is from the start of the program in January 2010 to May 2011 (Program Tracking data); and registration and National Minimum Dataset (MDS) data from January 2010 to June 2011.

The program data from the MDS includes basic demographic information and the number of case management hours provided to pilot participants. The Program Tracking data tracks participants identified needs and support types received to meet these. This data source also includes key dates and some basic budgetary information.

Most of the quantitative program data for this report are descriptive. The information has been grouped into categories where possible. There are a number of inconsistencies in the data: in a few cases, a participant with tracking information could not be matched to service usage data; and some participants had no information available. Budget information is calculated using average costs per service and per hour.<sup>1</sup>

---

<sup>1</sup> See Section 5 for additional information about budget calculations

Table 1.1 illustrates SDS participant numbers and data provided for each of the two pilot groups until June 2011.

**Table 1.1 Administrative data, group sizes**

Number of participants	Date	Children 0-6 years	Young adults 20-35 years	Total
Participants with registration data	2010-11	37	42	82
Participants with tracking data	2011	37	16	53
Participants with MDS data	2010-11	40	35	75
Participants with tracking, registration and MDS data provided	2011	34	16	50

Source: Program tracking data as at May 2011, registration and MDS data for July 2010 to June 2011

The registration data indicates that by the end of July 2011, 37 children and 42 young adults had registered with the SDS pilot, a total of 82 service users. The MDS data includes 40 children and 35 young adult participants.<sup>2</sup> These inconsistencies reflect missing data and difficulties linking some participants across the different program data sources provided. For clarity in this report, the source of information is indicated under each table.

### **Personal Wellbeing Index (PWI) data**

The findings in the baseline report were based on available program data and fieldwork data at June 2010. In this report we have included a third source of information, survey data analysis of the Personal Wellbeing Index (PWI) for the young people and family carers.

One of the key aims of the SDS pilot is to enhance the wellbeing of participants, young adults with acquired brain injury and physical disability and children with a physical disability, and their family carers and significant other supports. The program rationale is based on the assumption that linking people with disabilities and their informal supports with their local communities, and creating opportunities for meaningful engagement and participation will enable participants' independence and self reliance. Overall this may contribute to people's personal wellbeing and satisfaction with life.

### *Methodology*

The instrument used to assess the wellbeing outcomes for adult participants in the SDS pilot program is the Personal Wellbeing Index (PWI-A). The PWI is a validated instrument that comprises seven questions relating to 'satisfaction with life domains', about health, security, community participation, and others. Each question is answered on a zero to ten scale of satisfaction. Scores are commonly combined across the seven domains to yield an overall Index score (Cummins et al. 2009). For comparative purposes PWI group value means

<sup>2</sup> These discrepancies can be partly explained because the MDS reflects the previous reporting quarter and not actual number at time of analysis; also by some participants entering the program and exiting shortly thereafter.

---

scores can be compared to population data, or specific sub-groups, to gain insights into how a specific group is faring.

#### *Data collection*

For the purpose of this evaluation the researchers distributed different types of PWI surveys to the two service providers who then administered the surveys with the SDS participants. The researchers also used validated versions of the survey which were specifically designed for people with an intellectual or cognitive disability. These versions of the PWI survey use reduced scales, or simplified scales (smiley faces, sad faces) instead of numbers ranging from zero to ten. ABIOS service providers were advised to assess participants' needs, based on their professional expertise and relationship with the client, to determine the best suited survey for each respondent.

The aim was to complete at least one survey by July 2011 for one primary supporter for each child, and all young adults and one of their main supporters. Family members and informal supporters completed the survey assessing their own wellbeing and satisfaction with life. Due to ethical considerations no measure was completed for the child (0-6 years) cohort.

#### *Measuring change over time*

In the Evaluation Plan (Gendera et al. 2010) the PWI survey was to be administered at multiple points in time, once at program entry and if possible every six months thereafter, and upon exit of the program. However, for practical and administrative reasons the decision was made to collect surveys, where possible, at entry and exit from the program.

Service providers started collecting PWI surveys from adult participants in January 2011. Due to delays in rolling out of the surveys however this report does not contain any longitudinal (follow-up) data analysis. The longitudinal survey data will be collected in the second half of 2011 and analysed for the final evaluation report.

#### *Total sample numbers*

The PWI findings in this report are based on the following sample of respondents who completed the PWI measure in the first half of 2011: 19 of 42 registered ABIOS participants; and eight ABIOS family members and 33 of 37 registered SCCTC family members and informal supporters. The total survey response was 60.

#### **Fieldwork data**

For this second, longitudinal report participant interview data were available from a range of stakeholder groups, including Department staff, ten young adult participants and three informal supporters that were not analysed or conducted for the first report. For the second report researchers conducted nine interviews with mainly parents of children with physical and multiple disability; ten interviews with young adults, and four interviews with their

informal supporters. Researchers also conducted and analysed interviews with two service provider staff, one from each agency; and three Department staff (Table 1.2). Interviews were conducted in June-July 2010 and June-August 2011.

**Table 1.2 Longitudinal qualitative interviews 2010 and 2011**

	2010 baseline report		2011 second report		
	Children 0-6 years	Young adults 20-35 years	Children 0-6 years	Young adults 20-35 years	Others
Pilot participants	-	10	-	10**	-
Informal support eg. family	10	3	9**	4	-
Service provider staff	1	8*	1	1	-
Service provider manager	1	1	-	-	-
Department staff	-	-	-	-	3

Note: The qualitative samples supplement the full participant population quantitative datasets  
 \* Three interviews with eight ABIOS staff.  
 \*\*longitudinal (repeat) interviews were conducted with five of the 10 ABIOS participants; and four of the nine family members of children participants.

### *Data collection and quality*

To ensure an unbiased selection of participants we asked service providers to approach and invite the most recent families who entered the program to participate in the research. To measure change over time, participants who had been previously interviewed and were still in the program, were invited to take part in a second interview for this report.

It was challenging to obtain detailed information about participants' experiences for the baseline report, due to the short time some participants had been in the program. The second round of data collection for this report however provides good quality data for all participants who were interviewed and longitudinal, in-depth information for some, who were interviewed twice.

Another factor limiting the qualitative data collection for the baseline and this report is the sensitivity of the topic. Several families were still adjusting to their child's additional support needs, the families' circumstances, and contact with the social and community sector. To ensure participants' wellbeing and minimise stress, researchers did not use terminology such as disability or in some cases ask follow up questions if parents or young adults showed signs of distress.

Few observation data are included in the baseline and this report as most families chose not to have their child at the interview. This was mainly to ensure a smoother interview process. Additionally, most parents were time poor, juggling a number of caring duties and responsibilities (e.g. appointments for their child) with part-time work. These circumstances to some extent reduced the participant's ability to fully engage with the research.

Two rounds of interview data with young adults using the pilot provided through ABIOS are included in this report, as their data were not available at

---

the time of last reporting. Seven ABIOS informal supporters were also interviewed (see Appendix A Evaluation Methodology for an overview).

## **1.2 Report structure**

The report describes the program as delivered by the two providers and profile of the participants in Section 2, before presenting the findings. The outcomes evaluation findings are presented in Section 3. Section 4 examines the service effectiveness and Section 5 presents the analysis of program costs.

---

## **2 Program and support model description**

### **2.1 Aims of the Self Directed Support Pilot**

The Self Directed Support pilot has two key objectives: community inclusion and the empowerment of service users to make their own choices about their support (self direction). Self directed support enables participants, their families and other informal supporters to identify their needs, lifestyles and aspirations, and set personal goals. By giving people with disabilities control over their allocated funding, the program assists them to be their own agents of change (Department of Communities, 2010: 7).

An aim of the pilot is to enhance social and community inclusion of children and young adults with physical disabilities. Linking people with disabilities and their informal support with their local communities by creating opportunities for meaningful engagement and participation is regarded as a key to individuals' wellbeing and increased resilience. The program aim is to use strengths of existing community networks to enable participants' independence and self reliance.

The program's further objective is to facilitate participants' cooperation with the community rather than dependence on formal services to work towards their goals. Person centred support and community inclusion combined are seen as a form of early support and an alternative to formal services associated with crisis later on in life (Department of Communities, 2010).

### **2.2 Roles and responsibilities of the Self Directed Support Pilot partners**

The four main stakeholder groups in the pilot are children and young adults with physical disabilities and their informal support (family, carers and significant others); case workers employed by these agencies who work closely with people with disabilities and their families; nongovernment service providers funded by the Department to implement the program; and Disability Services and Community Care, Department of Communities staff who oversee and coordinate the initiative.

Governance arrangements between the NGOs and the Department include:

- Quarterly reports on service types for the National Minimum Dataset MDS;
- Detailed progress reports including qualitative and quantitative data; and
- Participation in quarterly consultations groups with Departmental staff.

### **2.3 Service delivery and service model**

The Queensland Department of Communities selected two service providers from a negotiated tender process to implement the Self Directed Support pilot. One is the Sunshine Coast Children's Therapy Centre (SCCTC) located in the Sunshine Coast, which supports young children (0-6 years) with physical disabilities and their family carers and significant others. The second is the

---

Acquired Brain Injury Outreach Service (ABIOS) in Brisbane, which supports young adults (20-35 years) with acquired brain injury and physical disability.

The two NGOs are funded \$240,000 per year for two years to deliver services under the pilot. The annual budget covers expenses for management, staff and operational costs; and person centred (self directed) planning and support, community inclusion, and early intervention for 40 participants, including self directed budgets of up to \$4000 per participant.

The core features of the service delivery include:

- A strengths based practice approach (eg. person centred planning);
- Good understanding of the nature of community connections;
- Planning, management and support of long-term community integration for people with disabilities;
- Collaboration and networking with a range of stakeholders to develop opportunities for community inclusion;
- Use of innovative and early intervention approaches; and
- Capacities focused approach to community development.

The Department selected the providers at the end of 2009. From January to June 2010 the providers established their operational systems and marketed the program in the community. By August 2011 SCCTC had recruited and supported 40 children and their families, and ABIOS was working with 42 young adults and their informal supporters. In total 82 children and young adults had participated in the SDS pilot, which is half of the targeted number for the pilot over two years as defined by the Department (40 participants per annum, per service agency). Some ABIOS and SCCTC participants have received a second round of funding.

### **SCCTC service model**

The SCCTC employs a part-time experienced services coordinator, trained in social work to case manage families and contribute to wider community development (eg. organise play groups to enhance peer support for children, family members and other informal support). The services coordinator is also in charge of promoting the pilot (eg. development of social marketing tools) and recruiting eligible families from a wide range of backgrounds, including Indigenous and CALD communities.

Children and their families are referred to SCCTC from a range of community and allied health agencies, including GPs, paediatricians, and disability services. Families can also self-refer. The range of referral sources are a result of the services coordinator's promotional activities. Once a family with a child with additional support needs has been referred to the SCCTC their eligibility for the program is assessed. The eligibility criteria are: children aged 0-6 years with a physical disability; not receiving other Disability Services; and living in the Sunshine Coast area. Families are either accepted to the pilot, or

---

referred on to other more appropriate services. Accepted families arrange a first planning session with the services coordinator, in most cases a home-visit. During this initial planning phase the family discusses and identifies their child's and/or the families' support needs. They also receive information and advice about a range of available support and how to best prioritise their needs and wants. When the family decides on a specific approach, the services coordinator assists them to access the relevant support they need. Part of this role is to coordinate a number of service providers, where necessary. The planning process and allocation of funding is reviewed every three months.

The SCCTC approach is to first meet the immediate support needs of the pilot participants. Then the aim is to assist families to identify and enhance existing and new informal community support and networks, to strengthen families' and persons' independence and self reliance. The aim of this second step is to build more long term support networks for pilot participants, beyond their direct involvement in the program and after the disbursement of allocated funding. A question for the evaluation is to observe whether this expectation is achievable. Due to the part-time Coordinator supporting a large number of families, the Coordinator has little time to do any program or community development.

### **ABIOS service model**

Young adults, aged 20-35 years, with acquired brain injury (ABI) and physical disability, receive support to take up the Self Directed Support pilot through ABIOS. ABIOS is funded by Queensland Health to provide specialist community-based rehabilitation to enhance the service system for people with ABI and their families.

The ABIOS manager manages the pilot and the rehabilitation coordinator and an ABIOS research and development officer support the project coordination. This management team together shares the responsibility for conceptual development, implementation of the model, approval of expenditure, staff training, and measuring outcomes. The project coordinator has day-to-day operational responsibilities to ensure case conferences and planning meetings run smoothly, while the manager maintains an oversight role and approves expenditure. The program is implemented by a team of ten ABIOS staff – the two managers, who also maintain a case load, and eight rehabilitation coordinators (case managers) who work with a small number of pilot participants alongside other clients.

Young adults enter the program through the already established ABIOS referral system, which is concentrated in the health and allied health system (no additional promotion for the pilot is conducted). Once a client has been referred to ABIOS, their eligibility for the pilot is assessed. Eligibility criteria are: aged 20-35 years; have physical disability, not receiving other funded Disability Services. If eligible, they are allocated a case manager, who begins to work with them on planning activities. The aim is to develop a plan prior to the allocation of funds against a goal, or strategies to meet that goal. ABIOS has refined the planning tools provided by the Department, and uses these to

---

structure planning and support activities with the pilot participants. Plans are scheduled for quarterly review. Case managers discuss clients' needs at a team case conference when the person starts on the program, has large changes to their plans, or has a request for new spending. The case conferences aim to share knowledge, insight and learning about the program.

The planning and spending process becomes iterative for many young adults in the pilot, with urgent needs met first, and case managers describing the need for major life goals to be broken into consecutive strategies for people to be able to tackle them. Some young adults plan to exit the pilot after completing the planning stage and spending their allocated funds. Other clients work with case managers on goals that focus on inclusion in their community in a way that is motivating and personally engaging.

## **2.4 Participant characteristics and target groups**

In this section we analyse available demographic information about the two groups using the pilot to assess the extent to which the program is meeting its designated target groups and any possible limitations.

### **Characteristics of the pilot participants**

Table 2.1 presents the gender and age distribution of SDS pilot participants by June 2011. The age range for children was 1-7 years old. The program is intended for children aged 0-6 year old. While this age range takes exit time from the program into account, this could also indicate that the program eligibility criteria do not meet children's needs, as identified in the baseline report (Gendera et al. 2011). More boys (26) than girls (15) are in the program, which is consistent with the baseline findings.

The age range for young adults is 20-36 years old (also taking exit time from the program into account), with the majority of participants aged 25-29 years (average age 28 years), consistent with the baseline. The gender imbalance also remains for young adults, with 74 per cent young men. The number of young women has risen from five to nine women since the baseline analysis. The gender distribution for young adults with acquired brain injury is consistent with the incidence of acquired brain injury among 15-24 year olds (O'Connor and Cripps, 2000, p.12-13).

---

**Table 2.1 Characteristics of pilot participants, June 2011**

	Children		Young adults	
<i>Age</i>				
Actual age range (years)	1 – 7.5		20 - 36	
Average age (years)	4		28

Note: Some participants were unable to be matched to demographic data.

---

### Target groups

The program is clearly reaching its early intervention target group for children. Most families in the program have children aged 0-2 or 4-6 years with less severe developmental delays and additional support needs. In most cases children's needs have been identified by a professional, but are rarely diagnosed. Most families prior to the pilot had not used or had little awareness of Department funded disability services, with some exceptions. A number of families are on long waiting lists for the Cerebral Palsy League and similar support services.

The main limitations of the program for children are engaging Indigenous and CALD families. The baseline report found that this limitation had been identified by the service providers and that they were planning strategies to reach out to these groups. However, to date, the SCCTC coordinator has had no capacity to dedicate extra time for further program development, such as engaging Indigenous and CALD families, networking and promotion; or community development for families in the program, such as setting up a peer-to-peer support group. The lack of capacity for non case management work is an on-going limitation of the program, and concern to the provider.

Some children and their families who could benefit from the type of support offered by the pilot are excluded because they do not meet the eligibility criteria. For example, children with more severe developmental delays are excluded because they do not have a mild or moderate physical disability, even though some of these children are not receiving other government funded support. Other children with intellectual or behavioural developmental delays (eg. autism or ADHD) are excluded if they do not have a physical disability.

The program is also reaching some of the target group of young adults with physical disability. ABIOS was funded to provide the pilot to young adults with both acquired brain injury and physical disability. All participants in the pilot have multiple impairments. The young adults come from a range of geographic areas within the bounds of the pilot area, and a range of socio-economic and cultural and ethnic backgrounds. Young adults in the pilot have

only been recruited through the ABIOS general referral stream, and concurrently receive other ABIOS case management services. The pilot has not been promoted to the wider community to attract other young people with disability. ABIOS services are promoted through a website, service provider training, publication, research and specific strategies for Indigenous and CALD communities.

### Entry and length of time in the program

Data available about entry and exit from the program are incomplete. Once the program was established, a steady flow of new participants entered the program during 2010 (Table 2.2). Fewer participants entered in 2011, because of the need to plan for transition at the end of the pilot.

**Table 2.2 Participants entering the program by month of entry**

Year	Quarter	ABIOS	SCCTC
2009	Oct – Dec 2009	1	0
2010	Jan – Mar 2010	8	6
	Apr – Jun 2010	12	7
	Jul – Sept 2010	4	13
	Oct – Dec 2010	4	6
2011	Jan – Mar 2011	0	3
Total		29	35

Source: Program registration data for Dec 2009 to March 2011

Note: the total numbers reflect the valid responses as some participants had no entry dates recorded.

On average participants spent 8-9 months in the program (Table 2.3). This average reflects the variation between participants who stayed in the program a short time to complete the planning and achieved their goals; and those who renewed for a second 12-month period, to continue to work incrementally towards long term goal achievement. This pattern was consistent for both the children and young adult groups.

**Table 2.3 Average time in the program by location**

	Clients	Average program length (days) (exited clients)	Average program length (months) (exited clients)
ABIOS	16	271	9
SCCTC	17	234	8
Total	33	286	9

Source: Program registration data for Dec 2009 to March 2011

Note: some clients did not have entry dates

This pattern of duration in the program indicates a likely sustainability of the outcomes because former participants are sufficiently secure to leave the program before the end of the 12-month period. It also reflects the priority of both providers to link participants to specialist and mainstream services in their own organisation and in the wider community.

---

### **3 Outcomes for children, young people and families**

A key objective of the evaluation is to analyse the outcomes and effectiveness of the pilot program for individual participants and their informal supporters. In this section, we analyse the extent to which the pilot program has achieved outcomes in the following three key domains:

- Enhanced individuals' independence and families' resilience;
- Improved participant's social, community and economic participation; and
- Generated long-term community connections and networks with lasting benefits to pilot participants and their informal supporters.

The analysis for this report is based on program data for all pilot participants from January 2010 to July 2011, and interviews with young adults, their informal supports and family members and carers of young children using the pilot (Table 1.1 and Table 1.2). This report includes the first analysis of the interviews with young adults and their supporters and analysis of Personal Wellbeing Index (PWI) data (Section 1.1 details the method).

#### **3.1 Enhancing participants' independence and families' resilience**

##### **Wellbeing, independence and resilience**

Both sets of participants, including families and children, and young adults and their supporters, reported improved wellbeing, independence and resilience due to participating in the pilot. These findings are consistent with the PWI data. Data from the PWI indicates that carers in the pilot have higher personal wellbeing rates when compared to Australian carers.

##### ***Young children***

All families reported increased wellbeing and independence for their children due to the pilot. Most of the young children in the pilot had only the beginning signs of support needs and their needs were usually classified as mild to moderate. For this early intervention group, parents reported frequently seeing rapid changes in their child's self esteem and self reliance as their motor skills and abilities improved. For example, when they entered the program some children could not walk, sit upright, or hold their head up. In some cases, children, after receiving a few weeks or months of intensive therapy and use of equipment, are able to progress to sitting, standing or walking. This progress enabled them to move to other development milestones and to become more independent.

Family members and informal supporters consistently linked improvements in children's physical health, wellbeing and development to the child's involvement in the pilot. Family members reported these positive outcomes as a result of referrals to regular contact with specialists, individualised therapies and equipment, and overall support provided through the services coordinator. A parent said,

---

It's been great, it really is intensive early intervention [our daughter is receiving] speech therapy, private physio, music therapy, orthotics, makaton resources, and a walking trolley ... The change in her motor development and coordination have been dramatic ... [they] are clearly the result of the intensive therapy and the orthotics, which are great.

Families who have received a second round of funding have seen the most improvement for their children. These informal supporters and parents also feel more confident to seek out further programs and activities that will continue the improvement shown. A parent said,

Since Simon<sup>3</sup> has had that trolley for walking, you can't stop him! He didn't want to walk before, now he's always using it ... It looks like he is catching up with other kids his age, development wise.

### ***Young adults***

Most young adults with acquired brain injury reported an increase in wellbeing and independence as a result of being in the program. They consistently reported using the planning process to engage in activities that built their independence and self-reliance. 'Increased independence' was interpreted by participants in a wide range of ways. Many participants have used the planning process and funding to take up exercise, join clubs or purchase equipment which is aimed at building physical strength and resilience.

Having access to tailored support was important to people, so that they could adapt their exercise requirements to their personal circumstances. Beth, for example, found home gym equipment to be of more use than a gym membership, as she would not be able to get there easily. She uses the home gym daily, and as a result is now walking independently. Beth said, 'Having the freedom to choose what suited us worked.'

In another case a young woman increased her independence creatively by using the funds to hire a dog trainer to train the unruly family dog. This helped her feel confident in walking in dog, enabling her to get out of the house, and more easily around the neighbourhood.

Participating in the pilot has given many of the young adults a new perspective on what they might do and activities to support their goals. Setting a goal, having the resources to realise it, and actively working towards its achievement, with some encouragement and support, has increased young adults' emotional wellbeing and self esteem, and in some cases also their mental health. Family and other informal supporters of the young adults all noted an increase in independence in the person they supported. They said,

---

<sup>3</sup> Note: pseudonyms have been used for all project participants and interviewees quoted in this report.

---

Before the pilot [he] was very depressed and often spent much of the day in bed ... Now, he's tinkering in the garage all day ... It's giving him ambition and drive.

It [the pilot] has opened his eyes to possibilities of doing things other than watching TV and drinking.

In some cases the increase in independence was physical – gains made through exercise programs, for example. In other cases, supporters talked about the emotional and psychological gains they observed. Several of the young participants themselves also spoke about the pilot assisting them to gain and maintain a better balance in their lives between addressing needs related to their impairment and participating in their community.

Many participants have used the program to support education goals, which have contributed to their emotional wellbeing, future financial independence and immediate participation in the community. When we asked young adults to reflect on what they had gained from their involvement in the pilot, most participants felt that they had increased their independence. Their comments included,

I know what I want in this life now, and I'm going to go out and get it. I'm amazed at how far I've got in two years.

Help, support, and the possibility of learning things and doing things I haven't been able to do before. To complete some goals I'd had in the back of my mind for a long time, but hadn't been able to do.

### ***Family members and informal supporters***

The majority of parents of children in the pilot reported positive outcomes for themselves, including increased wellbeing, which was commonly linked to a reduction in psychological and emotional stress and their sense of isolation. Observing the rapid improvements in their children's development and wellbeing gave the parents a sense of hope. They also found the information and coordination of support through the services coordinator very useful. One family said,

It's taken a huge amount of stress from us. It was such a relief to find this program. We'd been to see I don't know how many GPs and specialists and paediatricians ... and no one would help us or give out any information about how we can find support, and what type of support would help us.

The support model is enhancing family members' and informal supporters' independence by strengthening their sense of self esteem and self reliance as carers. The support model is enabling parents and carers to be experts on their children's needs and wellbeing, so they can actively seek out options for their children. As a result, some family members expressed increased confidence in their caring role. In one case, a mother's confidence was raised

---

through regular contact with practitioners who gave her practical advice and showed her specific techniques how to support her child's development. She said,

[Our son has] definitely benefited. And I think it's because ... when you have a week to week appointment, you [as a parent] have the space and time to do specific things with [your child], that gets the results. And you've got someone to check in with, if [your child is] not doing so well.

The flexibility of the pilot is also contributing to family members' independence, because they are able to use support and purchase items depending on their child's and the family's needs. A parent said,

There is that flexibility, to use [the money] how you want to. [without the money] it's very difficult when you already have a host of other appointments, where you have to do something that's fixed in a certain way.

Several families mentioned that participating in the pilot enabled the family to spend more quality time together as a family, '... trying to enjoy the children and trying to spend as much time with them as you can'. They felt that having the time and resources to spend as a family was an important factor strengthening family relationships and contributing to their family's resilience. This finding is consistent with child disability and family resilience literature (Muir et al, 2008). Some mothers have also used the impetus from the pilot to more actively address their own health needs.

Informal supporters and family members of young adults had a different focus to the family members of young children, and reported more about the pleasure they took in seeing the progress and satisfaction of their person they supported. The financial component of the pilot was important to informal supporters in resourcing goals and enabling participants to undertake activities which would not otherwise be possible. Some of these indirectly benefitted the family or support relationship, such as enabling a mother to have some time to herself during the week while her son was supported by a regular worker to complete some of his planned activities; or emotional benefit to the whole family of a holiday which was funded within the package. Participants' growth in self-confidence and willingness to try new things was seen by informal supporters as very positive, and with benefits to the relationship. Tania, for example, noted the pride of their children since Matt began woodworking and made his workbench, saying, 'Our two boys love it, and we have had to buy them their own little workbenches!'

These positive outcomes from the interviews with participants' family and informal supporters are also reflected in the analysis of the personal wellbeing survey data. The average PWI scores for informal supporters and carers of SDS pilot participants are similar to population data and higher than a national sample of Australian carers (7.2 for SCCTC carers; 7.5 for ABIOS carers; 7.5 Australian population; 5.9 Australian carers; Table 3.1). These findings are especially relevant when we compare the personal wellbeing scores of SDS

family members and informal supporters to Australian carers more broadly, as carers are known to be amongst the population groups with extremely low personal wellbeing (Cummins, Hughes, et al. 2007).

Cummins (2007: 4) analysed the wellbeing and stress levels of over 3700 carers in Australia. They found that carers in this study had the lowest wellbeing scores (5.9) compared to other identified demographic groups with very low wellbeing. SDS family members and informal supporters score on average 1.5 per cent points higher compared to the sample of Australian carers. These positive findings can probably be partly attributed to taking part in the pilot program.

**Table 3.1 Personal Wellbeing Index scores by groups**

	Family/carers children	Family/carers young adults	Young adults ABIOS	Australian carers*	Australian population**
Respondents	33	8	19	3,766	22,912
Mean	7.2	7.5	6.7	5.9	7.5
Minimum	4.2	3.8	2.9	-	-
Maximum	9.5	9.4	9.5	-	-

Notes: \* Data for Australian carers are from the Cummins, Hughes et al. (2007: 4). In the report PWI scores are reported on a scale 0-100 and have been adjusted here for the purpose of comparison.  
 \*\* These figures represent aggregated individual PWI data of total combined surveys from 2001-04. The data are from Cummins (2005).

We also compared participants who completed the PWI when they first entered the program or later (Table 3.2). The sample is too small for the results to be reliable, but they possibly indicate that satisfaction is higher the longer participants are in the program. Participants (carers and young adults) who completed the PWI survey within the first month of entering the program (6.5) had a lower PWI than those who were in the program over a month at the time of survey (7.2).

**Table 3.2 Personal Wellbeing Index by time in the program**

	Under a month	Over a month
Respondents	11	49
Mean	6.5	7.2
Minimum	2.9	4.3
Maximum	9.3	9.5

Note: not statistically significant (P=0.140)

The case management support and resources received to improve the independence and wellbeing of participants seems to have positive benefits for their families' and informal supporters. Both SDS carer groups have a high satisfaction in particular life domains and the scores are close to or higher than that of the overall Australian population (Table 3.3). The domains which can be associated with the pilot are: satisfaction with personal relationships

(more time 'as a family', family resilience), safety (additional resources), and feeling part of the community (increased participation).

**Table 3.3 Satisfaction with life domains by groups**

Satisfaction with...	Family/carers			Australian carers	Australian population**
	Young adults ABIOS	SCCTC - children	ABIOS – young adults	(age 36-55) *	
Respondents	19	33	8	~ 1273	22,912
Life as a whole	6.4	6.9	6.4	NA	7.8
Standard of living	7.0	7.3	7.1	5.7	7.7
Health	6.5	6.7	8.1	5.1	7.5
Achievements	6.8	6.7	6.9	5.0	7.4
Personal relationships	6.3	7.8	8.5	5.2	8.0
Safety	7.8	8.4	8.1	6.4	7.8
Feeling part of community	6.5	7.1	7.9	5.1	7.1
Future security	6.2	7.0	6.6	4.6	7.0

Notes: \*Data for Australian carers in the age of 36-55 years (Cummins, Hughes et al. (2007): 53 and authors calculation.  
 \*\* These figures represent aggregated individual PWI data of total combined surveys from 2001-04. The data are from Cummins (2005).

### Empowerment and coordination

The SDS model is based on person-centred service delivery to maximise responsiveness to the person's needs, coordinate their support and to empower the person and their family to take responsibility in relation to their support needs and other aspects of their life.

Family members of young children experienced the support received as strongly empowering. They particularly appreciated the recognition as experts in their children's care. They viewed receiving information and direction about available support during the planning stage as critical to assisting them to make informed decisions. One family said, 'We knew what we needed ... and [the services coordinator] helped us to work out what to get done.'

Participants perceived working in partnership with a committed services coordinator as the key to negotiating complex service environments and to help them prioritise their identified needs. All families who were interviewed twice were highly confident in their discussion about choices and how to plan to optimise their choices to achieve better outcomes for their child.

As noted in Section 4.3, families also highly valued the flexibility of the pilot to pay for a wide-range of identified needs, depending on the children's and families' changing support requirements. A parent said,

[It] is good that you know that there is a pot of money that you can review ... and we weren't stuck into some kind of program

---

that worked a few weeks ago, but isn't now, and that it can be dynamic.

While families have a good understanding of what they need and want, they said they often lack understanding about the range of available resources and support available, or they lack means to purchase them. In many cases the participants described the overall service system as disjointed and impersonal, making it difficult for families to negotiate their service pathways. Their confusion is aggravated when they are in the process of learning about the additional support needs of their child, which can, for some families, be full of anxiety. Hence, many families said that receiving personalised assistance through the pilot and having someone 'who listens and understands' is as critical as the access to support itself. They said it is through the assistance of the services coordinator that they feel empowered, informed and emotionally supported to access what they need. Parents said,

[The services coordinator is] really willing to help, to do anything that she can, which to me is so satisfying after seeing quite a few years of not having anyone wanting to help or listen.

As I said [the pilot] was just a breather for us to have someone who understood, someone who knew the sort of difficulties that we were facing. Because [my child's needs are] not as severe ... It's still constantly a thing on your mind of how are we going to physically, financially and emotionally manage this?

A further key to person-centred service delivery is that all professionals work together and coordinate their activities, where appropriate, to meet a person's needs. The strengths of such professional partnerships mean better and more rapid outcomes, in this case, for young children's development. In several cases, family members reported that the coordinated team approach had allowed professionals to draw in extra resources to meet their children's needs without having to rely on the funding allocation. A parent said,

The main positives [of the pilot] are the support that [the services coordinator] gives, as well as the planning process. Also the fact that all the therapists that we see are working together around [our daughter's] needs. The team approach is much more effective.

In the case of young adults with acquired brain injury with higher support needs participating in the pilot, person-centred service delivery is perhaps even more important. The role of the planning and casework elements of the program in making links to other, ongoing supports is important to participants and their informal supporters, as is the role of case workers in providing information about options which might be available longer term (such as employment, or ongoing funding for a regular support worker).

---

The individualised, person-centered and flexible nature of the program is a key to young adults' satisfaction with the program and their sense of empowerment. Empowerment to them was strongly connected to the degree to which young adults felt their ideas and goals were respected and supported. Most participants (13/15) felt that their case workers were supportive and enthusiastic about their ideas and planning goals, as in Phillip's case,

She's great. If she hadn't been there to push me and make me think about things ... She arranges, she takes up my hints, she's fantastic.

Another central aspect of the pilot is the quality of the relationship between the young adult and the case worker, and the workers capacity to coordinate and organise identified support needs. Most participants were either satisfied or highly satisfied with the case work arrangements. Young adults appreciated the rapport, felt supported and respected, felt workers were reliable and that they worked behind the scenes to make things happen. One young woman commented, 'She does what she says she is going to do, and that's important ... She has been there for the long haul.'

Two participants were dissatisfied with the case work arrangements to some degree. Their concerns were about the effectiveness of their case worker working in partnership with them, implementing their ideas for support and funding, and advocating on their behalf in team meetings. Although these two young adults raised some concerns, they still felt that they had benefited from the pilot.

Some of the young adult participants had traumatic or difficult histories, either due to their injury or other life circumstances, which they felt had reduced their sense of self-worth and esteem. They found the trust placed in them by the self-directed approach in the pilot, and workers' emphasis on decision making and control over allocated funding highly empowering.

### **3.2 Social, community and economic participation**

The program has improved the social, community and economic participation of the young children and their family members, including parents and siblings. Young adults reported large increases in community and economic participation. Many of the activities that participants identified as goals are community oriented, or located in the community, and therefore involved social interaction and engagement with other people. However, it appears that their gains made through social participation were limited so far.

As noted above, young children participating in the pilot have made substantial improvements in their motor skills and development, which enhances their opportunities for social connections in their families and communities (eg. play with siblings and interaction with peers).

The parents of young children consistently reported high levels of satisfaction and rapid outcomes for the child's development when professionals work

---

together around their child's care and needs. The individualised nature of the support is enabling some of the children of school age to take a more active part in school. A parent said,

[My son is] able to take part more in the classroom because of the OT coming to the school to do assessments and that. [These positive outcomes are happening] because of the support from [the services coordinator], and also because the OT and physio are working together.

Family members of young children noted that the program is providing them with access to a range of community support, in particular to specialist services and resources as well as equipment, from which they would have remained excluded otherwise. They viewed the assistance as critical to enabling the families' and children's involvement with their communities (eg. specialised adaptations to enhance children's school participation). Some of the parents reported that they are now able to pay for social and community activities for their other children, such as swimming lessons.

Several mothers reported accessing community programs or facilities to complement the pilot. An example was a mother enrolling in a course at her local library to learn how to use the computer purchased through the program, so that she could help her son with his motor skill development.

While the pilot directly addresses the affordability of their children's support needs, it does not resolve the economic complexities families may be facing. In some cases, where mothers are the primary carers, they have stopped paid work or decreased work hours to meet their child's additional support needs. It appears that over time, as a result of children's improved wellbeing and independence, some primary carers have been able to increase paid work again.

Nevertheless the incompatible challenges of remaining highly flexible in their caring role, paying for disability related costs and remaining in a labour market that demands long working hours, add to pressure on families' budgets and resilience.

Young children and their families experienced the following key community inclusion outcomes:

- Care and equipment supported children's positive development and wellbeing and social and community participation eg. school attendance;
- Children's positive outcomes contributed to families' resilience and positive family relationships eg. such as primary carers having more time for their other children;
- Families were connected to community supports and specialist services eg. through the information from the case coordinator.

- 
- Some families have avoided entering a crisis and social exclusion. In the extreme, one family said the coordinated support and funding prevented them from selling their home to pay for their child's specialised therapies; and
  - Some primary carers who have had two rounds of funding in the program have been able to resume paid work again, as a result of children's positive outcomes eg. that mean that they can attend child care.

For young adults participating in the pilot, the social community and economic participation outcomes are even more direct. Young adults reported large improvements in their community and economic participation. Many of the activities that participants identified as goals are community oriented, or located in the community, and included social interaction and engagement with other people.

Young adults' economic participation increased through purchasing goods and services from their allocated funding, but also through focusing on career development, with the aim to increase their employability over time. Many participants have signed up to TAFE courses or other professional and personal development opportunities. All the participants who were studying said they found it valuable. These activities and pursuits improved the young person's social and community participation and were likely to contribute to their enhanced economic participation in the long term.

The gains made to social participation were limited so far. Several young adult participants noted that the primary social connections they made through the pilot were to their case workers, service providers and other facilitators. Young adults had few examples of ongoing social relationships which had developed from activities within the pilot. One carer questioned whether the support provided to participate in community based activities was leading to relationship development. She said, [The support worker] is good company, they get on well, but when the funding ends in November, what's changed?'

### **3.3 Community connections and networks**

One of the pilot's objectives is to enhance and connect participants to informal forms of support beyond the program.

The majority of the families of young children have had limited if any prior contact with the social service sector before joining the pilot. Many parents are interested in exploring networks and resources once they commence the planning process, and most families are on waiting lists for on-going support.

In the early stages of the pilot, families prioritised meeting their children's immediate support needs over identifying additional forms of informal and community support. However, as they spent longer in the program, many of the mothers requested that their contact details be passed to other mothers in the program for networking and peer-to-peer support. Some have made direct requests to set up a playgroup or coffee morning to share ideas, information and resources.

---

Families are also actively seeking out and participating in activities in their local communities, such as attending the local library, swimming lessons at the local pool, and bike riding in local parks. With increased knowledge from the program, they were also investigating their eligibility for additional services.

The major challenge to the capacity of the SCCTC model to enhance families' long term community networks is limited staff availability to coordinate and develop this aspect of the program (see Section 3.4).

None of the young adult participants reported developing long term social networks beyond the contact with pilot staff, perhaps due to the short term nature of the pilot. The activities, equipment, memberships and educational opportunities pursued through the program may contribute to social network development over time. For example, several participants mentioned in the second round of interviews that they were waiting for TAFE courses to start, and they expected to meet new people then.

Some people were also progressing with the incremental steps towards social network development. Simon talked about how he is bumping into people he can talk to at the gym more frequently now, but has not been for a coffee or to a BBQ or anything with them yet. This may happen in time, particularly if it is articulated in the planning process if he is keen to pursue this contact further. The gains in confidence and empowerment made by participants through the program can also be expected to improve their capacity to develop social networks.

Some of the young adult's goals are clearly aimed at supporting and developing social networks. For example, in deciding whether or not to use her funds to buy a trike, Lucy checked with a friend,

I rang up my friend, and I said 'You know what, there's a chance I could come bike riding with you if I bought a trike. What do you think? Would you be caught dead riding beside me with a trike?' And she laughed and said 'Yeah, do it, for sure! That's cool! And then you'll have this big rack on the back where you can put the picnic hamper!'

Some participants had used funds for family holidays, passes to theme parks, and one was planning to use funds to travel to her country of origin for a holiday. All of these goals were about strengthening family bonds and exploring opportunities for reconnecting to and engaging with members of the wider community.

People who already have social networks have benefitted from achieving goals that strengthen these networks. It is less clear whether the pilot has been able to forge new social networks for participants. Building new networks is a complex long term endeavour, and establishing a presence in the community is probably an essential first step in social network development. A clear advantage of the ABIOS model is that case worker support for participants will continue at the end of the pilot, enabling these

---

participants to continue to build on the foundations laid with the SDS funding and planning. Implications for the pilot, may be that the long term nature of social network development, particularly for isolated people or people with higher support needs, requires the early development of informal social support circles or the active referral into ongoing support services.

### **3.4 Outcomes implications for program and evaluation**

It is clear that flexibility, planning and coordination of a person's needs, a person centred service delivery approach, and empowerment are central to the successful implementation of self directed support programs.

The interviews reveal that the program is achieving its goals of improving wellbeing, independence, resilience and social participation of participants and their family members and informal supports.

The program is also contributing to community connections for sustainable support and economic participation for young adults and families. This is most challenging for young people without existing social networks to build on because developing new networks is a long term activity.

## 4 Service use and effectiveness of service delivery

This section addresses the effectiveness of the pilot support model, and draws implications for program changes and improvement. This includes analysing the responsiveness of the model to meet participants' needs; the extent to which the model facilitates self directed decision making and control over allocated funding; and the extent to which it builds on participants' and families' strengths and capabilities.

We examine the development of the program from the establishment until July 2011, and the characteristics of the pilot model, including the partnership and governance arrangements. The sources of data used to address this part of the evaluation are interviews with key stakeholders, program observation and Departmental and program data from the service provider and MDS.

### 4.1 Service use

The two groups of pilot participants have very different needs and use the program in diverse ways. The following section summarises the available MDS and program data about participants service use from January to June 2011. It summarises the amount of case management children and young adults received as well as the different needs identified by each group.

#### Case management

The hours of case management received for all participants ranges from less than an hour to nine hours per week per participant. The median of one hour per week in the first quarter remains constant over the four quarters. Looking at hours of case management support received by each group it becomes evident that young adults in the pilot have very different and higher support needs (Table 4.1).

**Table 4.1 Change in average hours of case management per participant per quarter**

	July-Sept 2010			Oct-Dec 2010			Jan-March 2011			April-June 2011		
	Range	Median	N	Range	Median	N	Range	Median	N	Range	Median	N
All	1-5	1	47	1-6	1	54	1-3	1	55	1-9	1	56
Children	1-1	1	22	1-2	1	26	1-2	1	29	1-1	1	30
Young adults	1-5	1	25	1-6	2	28	1-3	1	26	1-9	1	26

Source: MDS data for July 2010 to June 2011

Note: Responses less than one hour were rounded up. Some participants were unable to be matched to MDS data.

In the children's group, families consistently received one to two hours of support per week across the four quarters. An explanation for this consistency may be that families' support needs generally remained similar over time eg. access to specialist services and equipment for their child. It may therefore be easier for the worker to provide more consistent planning support. Some families in the children's group also sometimes need some months to fully engage in the planning process, due to a range of factors such as family

---

relationships and emotional readiness. The narrower range of case management hours received by children may be an indication of the restricted capacity that the sole part-time worker can allocate to each family.

For young adults, their identified support needs varied and changed throughout their involvement in the pilot. Case notes for the young adults with lower amounts of case management, such as one hour per week or less, record some problems contacting participants, for example, participants' not returning calls or missing appointments. These issues are often common for people with acquired brain injury.

It appears from the available information that the case management allocation in both models is responsive to the participants' needs, availability and readiness to fully engage. It varies by the amount of time a person requires and it changes over time as their needs change.

### **Types of support received**

As noted earlier, the program data indicates that children and young people in the pilot receive and require different types and modes of support. In the planning process participants (or their families in the case of young children) are asked to identify three needs in order of priority. Many participants recorded three needs and some recorded fewer. This appears to be because their needs are more complex or costly than other participants, or that they had not identified all their needs when the program data were provided for analysis. Between the 46 participants with any needs identified and recorded, 145 individual supports were identified. Table 4.2 details their support needs in order of priority identified by the participants and their families for young children.

As expected, participants – particularly in the young adults group – identified a wide range of support. The most common needs for children and their families are therapies (physiotherapy, speech or occupational therapy). In some cases the children already received the support and the identified need was to continue with the treatment, when they could not afford them because they are no longer eligible for free therapy or they could not afford more. In other cases the program enabled the purchase of new therapies. The second most common need is equipment, which is usually related to the therapy received by the child. Many children also had a third need identified, and these were concentrated on community involvement or family activities, such as swimming lessons or transport.

The commonalities between participants in the young adults group were education and fitness. Educational needs are rated a high priority, and many young adults were using their funds to pay for costs associated with study, including books or computers. The second important priority is increasing personal fitness, participation in sporting activities that may contribute to a person's wellbeing, and also foster community participation. Young adults have a wider range of support needs than the children in the pilot. Education is a priority for many young adults. They said in the interviews that they were very motivated by career development, and made use of the pilot to redevelop

their career post-injury. These activities were also linked to increased social and community involvement as a priority across the group.

**Table 4.2 Needs identified by participants in order of priority**

	Number of participants identifying need in order of priority			Total participants with the need
	Priority 1	Priority 2	Priority 3	
<i>Children</i>				
Physiotherapy	27	1	0	28

Note: Totals do not represent all participants because some participants did not have a need identified, and some clients were not included in the data				

## 4.2 Participation in organising support

In this section we analyse the extent to which processes in the pilot model empower participants and their informal supporters to make decisions about their needs and goals.

In SCCTC, the planning process is used by the services coordinator with the families to identify options and to provide them with a range of information

---

about resources they can access, either through other programs, or by drawing on their funding allocation. Families of children participating in the pilot reported that they feel a sense of control over their allocated funding, and support in the process of setting and prioritising goals. They said,

We were seeking a bit of direction, so it was really useful to have the planning document and process, to talk things through.

We worked out together that he [the son] would need some activities, and we both thought about the types of activities, and worked it out from there.

Most families are actively discussing their options within the family, and taking charge of planning and prioritising (Section 3.1). Interviews with families showed continuing high levels of satisfaction with SCCTC's approach to planning to set and implement goals and drawing on the funding when necessary.

Young adults approached the planning and goal setting process in a wide range of ways. Some participants spoke about living in the moment and dealing with their circumstances on a daily basis. For them plans were centred on making changes to their immediate situation, including increasing their fitness, dealing with chronic pain or frustration, and adding more activities to their schedule to have something enjoyable to look forward to do.

Many young adults were focused on getting back to work, or learning new skills. In a few cases young people were thinking and planning more independently and creatively about how to use the funds and support as a springboard to future personal success. Dean, for instance, had career plans that required completing several inter-related courses. By the end of the second round of funding, he had done two of the three courses. In Lucy's case, she is using the planning and funding to learning skills to develop her own business. She said,

When I first found out about the pilot, I was so excited, I thought 'wow' this is amazing, I can do this, and this! ... But I realised it [the funds] goes very quickly. And is it really going to end up helping me to continue where I am, or am I going to fall in a heap at the end when I've spent it all? And I didn't want that to happen, so I tried to space it out, so it's like a little infusion here and there where I'm needing it, and that's working really well for me.

At its best, participants described a partnership approach to planning and decision making with their case workers which supported and extended the goals they identified. A few young adults were seeking new direction but were less sure of what they wanted to do, and had used funds to explore different options.

---

Some young adults were unsatisfied with the planning process. Two participants wanted to use their funds for speech therapy, but said they were told it was not possible within the program guidelines. They found this frustrating, as they felt communication difficulties were their biggest barrier to independence and social inclusion. A third participant does use the funding for speech therapy. Three participants said they had other planning goals refused that they had felt were consistent with the program. It is difficult to know if there may be other reasons for this without knowing the planning process behind decision making, such as prioritising limited funds, for instance.

In the early stages of the pilot implementation, some ABIOS workers were concerned that some people with acquired brain injury would struggle to make responsible spending decisions. Another concern was their ability to scaffold activities (or sub-goals) in the planning process, and the need to align goals to the program objectives to remain within the program guidelines.

To address these risks, ABIOS implemented a risk assessment process to support young people in their planning process. This focuses on a careful planning process, training for workers, working through decisions with participants and the team meeting review process. From the interviews with workers and young adults it appears that this process has been carefully implemented, is respectful of individual difference, cultural diversity, and is well integrated with the principles of the program. Young people and ABIOS workers provided many examples of creative solutions which mitigated risk while at the same time maximising participants' choice and control. There were some limitations to autonomy from the point of view of participants, notably the team meeting review process (Section 4.3).

As illustrated in Lucy's case above, most participants interviewed had a clear sense of working step by step towards a bigger goal – education as a step towards work, or starting with an exercise physiologist to get strong enough to join a community gym class, for example. Matt's plan is a further example. He asked that the plan and photo be included in the evaluation report.

Matt is about to start a woodwork course, to develop his skills in making small pieces of furniture and other items. He and his wife plan to start a small online business to sell these once he gets on his feet. Matt has used his funding to purchase some tools and wood, and is doing voluntary work with a furniture maker while waiting for his course to begin. He was a bit disappointed not to be able to use a Bunnings gift card to buy woodwork incidentals under the rules of the program, but understood it was outside the guidelines\*. He downloaded a plan for a workbench from the internet while waiting, and made his own workbench and set up a workshop in his garage, so he would be ready to go with his business.

\* The use of a Bunnings gift card is within program guidelines; however in this circumstance the parameters for its use was considered within a risk assessment context for the client in question.

---

**Figure 1: Matt's workbench**

Most ABIOS participants were satisfied with the approach to risk management taken within the pilot, except when the financial rules caused delays or inconvenience (Section 4.3). The two participants discussed above were not satisfied that they had sufficient input into the decision making process about goals which carried a level of risk.

Another possible limitation to the effectiveness of the planning process was the complexity of the staff and participant relationship, and the power differential between case workers and clients. Some ABIOS participants expressed gratitude for the funding and support, and were reluctant to make demands on the pilot, raising questions about the degree to which they would feel prepared to push the planning process. The power differentials between team and clients, in the very best of professional relationships, require careful and skilful management in order for people to feel they able to make demands in a time pressured environment. To the credit of the professionalism of the ABIOS case workers, most participants felt the case worker contact was appropriate; they were able to contact their worker whenever they wanted to, and could get a quick response.

The developmental approach taken to planning is a key strength of the pilot. The measures implemented by ABIOS, including training staff in person centred planning; planning processes which are individualised and flexible; and additional resources for workers to overcome difficulties, where identified, have proven to be a very sound approach to developing a solid planning structure.

ABIOS participants discussed their understanding about the need to be prudent in their management of limited finances, and provided examples.

---

Cameron said, 'I'm not going to use the money just to use the money, you know what I mean? If I use it, I want to use it for something beneficial.' Staff and policy makers shared this view. Policy makers also stressed the importance of funding for 'non-traditional forms of support' as an integral part and underlying philosophy of self-directed support.

Workers reported that the major limitation undermining the success of the planning approach for some participants was the short timeframe of the pilot. Young people are at different levels of readiness to plan and progress, hence the process may require different amounts of time and levels of support.

### **4.3 Funding allocation**

The program includes up to \$4000 per year to support each participant's plan. In the previous section we described how this arrangement has empowered participants (Section 3). This section examines process issues arising from participant experience and program data.

SCCTC has added to the mixed approach to managing the funding allocation since the Baseline report. In addition to reimbursement of expenses to families and payment of invoices directly to providers of goods and services on behalf of families, SCCTC also offers families the option of self-managing their funding if they wish. One family has used this option.

Most SCCTC families indicated that they were happy for the money to be held by the service provider, as they felt it would take too much time to manage the money and account for expenditure. They also questioned whether the money would need to be included in an income tax declaration, and whether a separate bank account would need to be set up. The service provider also raised the issue of GST and the fact that the service provider is registered for GST and receives this money back, however if individuals were paying for services and equipment, they are not registered for GST and so essentially this would reduce the amount of funding to \$3600 for families who chose to hold the money themselves.

Irrespective of the choice for managing the funds, SCCTC parents suggested acquittal balances be sent regularly via email or posted to families (monthly, rather than the current quarterly system) so that parents could better understand how much money is left in their funding budget. One mother was critical of the timeliness of the process for receiving reimbursement of funds spent by the family, and receiving an updated balance of the amount of money spent. She said,

This is the one thing that I am disappointed in the program about. Maybe there might need to be some guidelines or policy around this when you enter the program, so you know when exactly you will be reimbursed and told of the balance. It would be better if the Government could do a reimbursement system like Medicare for this program – you just go into a local branch and get a refund.

---

Young adults using the program were responsible and prudent in their approach to planning and spending of funding. All participants felt that access to the funds was a great opportunity to resource their goals, some of which they had held for some time. All participants expressed appreciation for their inclusion in the pilot, and valued their involvement. Two participants were reluctant to spend the whole funding package, so as to leave funds for other participants who may need it more. Most participants were unable to specify the amount of funding they had used or which remained. Some were able to estimate to within a few hundred dollars. Keeping across this level of detail may not be seen as being important for all young adults. However, all indicated that they felt able to call their case worker and ask how much funding remained.

The participants interviewed in the second round (2011) commented on the opportunity to self-direct funds. Some people had discussed this option with ABIOS, and one participant had recently taken up the self-management opportunity. She talked about seeing the benefit of what she has achieved, and how it guides her planning now. She said,

I feel responsible, and that I'm moving forward in an organised fashion. I think I can see the benefits of it more than I did earlier, and see the benefits of what I've been able to achieve.

Managing her own funding, she found it simultaneously liberating but also isolating. She suggested that it would be helpful to continue to have more frequent contact with her case worker, to be able to bounce ideas off someone before making her decisions.

Other participants preferred that ABIOS continue to hold and administer the funds, while they had control of the decision making process. For some, this was due to the level of trust established with their case workers. Two other young adults felt that holding funds directly would be a burden and worry that they would prefer not to have.

ABIOS managers report that six clients are self managing their funds, five in part, and one client managing the whole allocation. The clients who are partly managing their own funds average a 50 per cent split of self- and ABIOS-managed funding. Another three clients have declined the offer of self management, one due to concerns about tax implications of the funding, and the other two because they were satisfied with current arrangements and preferred ABIOS to manage the funds.

The funding allocation arrangements for young adults are subject to the Queensland Health finance rules because ABIOS is a government health organisation. The rules are strict, requiring invoices to be raised, restrictions on the use of petty cash, and other high-level administrative processes to ensure financial accountability. It is difficult to fit the program within this financial system where the funds are spent on non-traditional purchases and through processes that empower the young person to make the decisions, choices and purchasing. Reimbursement to participants is difficult to arrange,

---

and there have been delays in the purchase of equipment and services due to the time taken for departmental approval processes.

These limitations to independence and participation in purchasing inhibit the program effectiveness from the point of view of participants. While they are highly satisfied with the program, its processes and outcomes, participants consistently raised the problem of delays in the obtaining of goods and services and limitations to the ways in which purchasing could occur as factors which they felt could be improved. ABIOS workers, managers and government policy stakeholders also support these views.

Some participants suggested changing the administrative arrangements, so that finances could be organised more quickly, and waiting times for goods and services are minimised. For example, people did not want to have to ask shop cashiers to phone ABIOS for a credit card number to buy equipment which is part of their planned expenditure. To some people, this was demeaning, and they felt required them to explain about their brain injury and the SDS so that they were not under suspicion of credit card fraud.

The main problems arising from this structure relate to strict regulations (unrelated to SDS) of how funding allocated can be spent through Queensland Health, and young adults not being able to take direct control over their budgets. ABIOS case managers have previously suggested that participants would be more empowered by having increased control over purchasing. The views of participants and government stakeholders are consistent with this.

Most people who participated in the repeat ABIOS interviews said the control they felt over planning and spending had increased. The one exception was someone who wanted more information about options available, such as work, more efficient support, and greater control over funding. Four participants were satisfied in the first interview, and indicated increased satisfaction in the second interview.

The ABIOS process of discussing funding decisions in a team meeting for discussion is not constructed by the ABIOS management team as an approval process, but rather an opportunity for staff to discuss difficult issues, brainstorm, and to validate and affirm staff in their support of the decision making of clients (see Baseline report). However, participants consistently viewed it as an approval process where the formal decisions about their spending proposals are made. Several comments by participants illustrate this,

I put my ideas forward, and she said 'that *should* be OK, but I'll ask the board, you know, the group of people who are in charge of deciding what the money actually gets spent on.'

[caseworker] thought it was a good idea, and she confirmed it with the headmaster [ABIOS manager], and they thought it was a good idea.

---

[caseworker] said 'OK', she'll just have to check to make sure they're allowed. She just didn't give me a definite yes or no, she said 'I'll check, and once I've checked, I will let you know.' And she rang back and said 'yeah, we shouldn't have a problem with those' [goals].

Program participants' understanding that financial decision-making rests with the ABIOS management team restricts the effectiveness of the pilot, because it limits their opportunities for self-direction.

ABIOS has responded to these constraints on program effectiveness by implementing several strategies to minimise delays and increase flexibility, ranging from the use of a credit card to increase purchasing flexibility, to offering participants in the program the opportunity to self-manage their funding.

SDS is designed as a non-recurrent program. Nonetheless, this design limits the way participants can plan, and negatively affects people with higher support needs, who are most likely to require ongoing support to access activities and community-based initiatives. ABIOS workers and managers raised this as an issue early in the research, and it has been confirmed through the experience of pilot participants.

Policy makers and participants both echoed their preference for a longer period of funding and support to achieve sustainable outcomes. For example, a young woman has been in the pilot for two years (representing two separate intakes) with the same case worker. The first steps were small indirect tasks to eventually regain her apprenticeship. The funds were used for a computer and driving lessons. She now has a job, house and transport, contrasting sharply with her difficult circumstances before the pilot.

#### **4.4 Supporting early intervention and innovation**

The pilot model is designed to support early intervention and innovation through case management, community engagement and a small funding allocation. This section examines the participant and worker experience of these goals of the model.

##### **Early intervention**

The pilot is designed as an early intervention initiative. In particular the pilot aims to support children, young adults and their families previously not accessing or excluded from other formal assistance, and to young children who are showing early signs of additional support needs.

SCCTC children and families continued to experience the program's early intervention focus as described in Section 3.1, resulting in improved outcomes for children.

For ABIOS clients, the concept of early intervention is relevant to the onset of impairment, rather than chronological age. Participants in interviews who were

---

new to receiving supports or services in the disability or health fields (either newly injured, or whose other service contact had been with the criminal justice or homelessness systems) expressed higher satisfaction with the support provided through the pilot than those who have been involved with disability related supports before. In comparison to hospital, outpatient physiotherapy and rehabilitation, criminal justice services and homelessness outreach services, participants found the SDS program to be very flexible, person centred and respectful of their preferences, needs and goals.

### **Innovation in service delivery**

A second program goal is innovative service delivery. SCCTC families and children remain positive about the innovative aspects of the program, including the way it supplements existing child and family support and enables a holistic approach to supporting the family.

The ABIOS case managers had previously described the innovation of the pilot in taking the ideas of young adults that did not fit into traditional disability services and resourcing them to occur within the context of informal supports, free services, courses and generic facilities.

When asked what they liked best about the program, many of the ABIOS participants spoke about the program's capacity to promote their empowerment and connection to community. For example, they said,

That it's [the program] looking at me. You know, most services say 'this is what we provide, do you fit into that, yes or no?' This is tailored to me, rather than trying to fit me into what they do, or what they want to fund.

All the programs that come to the hostels say they are about getting you into the community, but this program is helping me get into life, not just the community.

The ABIOS participants who had a good rapport and relationship with their case workers felt they were encouraged to develop innovative ideas to use their funding. Some people were more ready to engage with developing innovative opportunities than others. Where it appeared that people relied more on their case workers to suggest options for their goals, they used more formal arrangements, such as courses, community classes, and gym memberships. Where they took a lead or more active partnership in the planning and implementation of support process, more innovative solutions were also in play, such as an iPhone to support a budding entrepreneur and driving lessons to prepare for work opportunities.

## **4.5 Partnerships**

The SDS model relies on partnerships between practitioners within the organisation to plan and administer the program; and with other service providers, to promote the pilot, strengthen referral pathways, and for professional development and information sharing. The pilot is designed as a

---

medium-term intervention with a small funding allocation to each participant, which means that referral and coordination with other support services is likely to be necessary to fulfil their needs.

The team relationship between case managers in ABIOS is more complex than in SCCTC, where there is only one service coordinator and her manager. Both service providers continue to see value in their approach. The SCCTC services coordinator values the opportunity to spend her entire professional role on the SDS pilot project.

The organisational isolation of the services coordinator from the rest of the SCCTC staff has limited effective professional peer support, mentoring, and information sharing. In ABIOS, the team of ten case managers meet three times a month to discuss issues relating to the pilot, working through key problems and strategising solutions. The ABIOS team stress the opportunities for peer review and input on difficult decision making issues and planning concerns that come from a large team approach to pilot. They also see the approach as a support to governance, in that individual case workers are helped by the team review process to develop a rationale to justify planning and expenditure which is non-traditional.

Partnerships between the pilot organisations and other service providers are also important to the pilot's process goals of coordinated care and sustainable service delivery. The approach to partnerships between the pilot organisations and other services providers has not noticeably changed in the period since the Baseline report. SCCTC had identified a goal to extend partnerships by seeking linkages with other service providers to extend the pool of therapists and practitioners. The worker has not acted on this plan, due to time pressures on a single coordinator to implement the program. Some community development work was done in the establishment stage and the manager of SCCTC supports these activities.

ABIOS continues to operate within the same model, primarily partnering on the provision of goods and services through the pilot. Participants noted some linkages with other community organisations, where they had been linked for voluntary work.<sup>4</sup> ABIOS recruits participants from their usual referral streams because this method is sufficient to fill the available places. The approach means that strategies for recruiting people not already linked into the service system are untested for this element of the pilot. ABIOS case workers continue to work with participants after they leave the pilot, which removes the urgency to develop partnerships and referral links.

---

<sup>4</sup> Interviews with case workers were not conducted for this report, which could have identified other new partnerships.

---

## 4.6 Process implications for program development and evaluation

### Lessons from the SCCTC model

The SCCTC services coordinator role works well supporting families to identify a range of available support and prioritising how to best meet their agreed goals. It builds on the coordinator's local knowledge of services. The planning process requires great sensitivity, especially for families who are still adjusting to understanding their child's needs. Parents want to be seen as experts of their child's support needs and to make informed decisions about how to best address these. The planning process and the provision of information empower family members and carers to take charge of their situation, and to actively seek out resources and information related to meeting their child's needs. The families are able to more effectively engage with other service providers as a result of this process. The coordination of individual support identified by the families appears to have had a high degree of success in outcomes for children taking part in the pilot – families have reported rapid improvements in their child's development, as discussed further in Section 3.

As the number of families entering the program has increased, the time that the coordinator has available for any work other than direct client contact has decreased. The part-time position does not have sufficient time to fully meet the needs of the families, develop partnerships and networks or complete the administrative requirements.

The isolation of the services coordinator from the rest of the Centre's activities means that she can focus on the needs of this group of families, but does not fully take advantage of the co-location with similar programs. For example, other SCCTC staff and programs have the potential to contribute linkages, peer review, support and professional development.

Policy and procedure development is needed in relation to the financial and administration of the program, including communication with participants. A gap identified by the coordinator was an information booklet about the planning process, particularly about how to involve children in planning. In response to this gap, the SCCTC has been provided with funding of \$33,200 to develop this information booklet. Program development, such as peer support and group responses to needs could be examined.

The program could have been more effective if partnerships had been fully developed, for example, when the local paediatricians and local GPs are fully aware and understand the benefits of the program, so that children could be referred for support as soon as the developmental delay is identified. Implications of not partnering with a range of stakeholders include less awareness about the program from stakeholders who might refer to the program and fewer options to address the variety of support needs, particularly low cost options.

Other restrictions that continue from the current program design are the limited funding allocation, in particular, for children with higher support needs,

---

and the exclusion of some groups of children from the program, such as children aged older than six years and children without physical disability and diagnosed with an intellectual disability or behavioural problems.

### **Lessons from the ABIOS model**

The team approach to case management has brought benefits of peer support, integration with other support offered by the organisation and quality control. The stepped process for goal development which case managers describe for people with impaired decision-making capacity provides, at its best, a supported and facilitated process of personal development for participants. Participants in the pilot felt that their plans were self-directed, and that they explicitly developed their own goals. Case workers filled in the gaps in meeting those goals, by providing pathways to move towards major goals, or suggestions and options about ways to reach goals. While participants still felt that their ideas needed to be approved before being able to be implemented, they clearly felt the program was in place for them to develop their own ideas about participation and activity.

Having resources to enable plans to be activated continues to be a key enabler of the pilot. For some of the participants in the repeat interviews, a clear developmental pathway can be seen between each year of the program. For example, Dean has used his funds to resource a series of inter-connected TAFE courses which he is completing in order to retrain in a new career after his injury. He completed one in the first year, the second in the second year of funding, and is now embarking on the third. For some participants the developmental pathway is less focused. For participants who have recently commenced on the pilot after being fairly newly injured, access to individualised planning, support and resources outside of the medical setting has made a great difference to both their physical recovery and emotional wellbeing.

The ideas of participants for improving the program were primarily about streamlining administrative and resourcing processes, and greater responsiveness to individual preferences. An example here concerns the development of a framework to support the tracking of expenditure for those clients who self manage funds.

Pilot participants concurrently receive case management from the same case worker who supports them with SDS. This case management role will continue beyond the life of the pilot. The good practice in this approach is that participants will retain ongoing support and planning over time. Most participants placed importance on their relationship with their case worker (Section 3.1), which is a consideration for the development of the program into the future, particularly if access to funding was to continue to be time-limited.

The financial rules for funding expenditure through a government health department continue to restrict the effectiveness of the program for ABIOS participants by causing delays to the purchase of goods and services and preventing them from receiving timely reimbursement or cash advances for

---

purchases in their plans. ABIOS has actively worked to minimise the impact of these government department finance restrictions.

### **Children and young adults most and least likely to benefit from this model of support**

According to service providers delivering the pilot, the support model is most useful for young adults, children and their families who previously had limited contact and were unaware of available support services.

The families of young children who have a good understanding of children's developmental needs and what support services could meet these needs, and the confidence to speak up and negotiate the service system benefit quickest.

In addition, families struggling to meet their children's needs also benefit greatly from the program, specifically from the planning, coordination, and information provision that the services coordinator role provides. Some of these families may find it difficult to make the best use of the funding allocation, because they may not have the capacity to understand, follow up or go to the numerous practitioners or support services from which their child could benefit. However, the assistance has been beneficial for child and family wellbeing and resilience for these families too. The funding allocation is not sufficient for children with higher support needs who are waiting for access to other free or subsidised support services.

The view of workers supporting the young adults is that young adults who already have established goals, or who are self-directed, are more likely to benefit quickly from the pilot. Some young adults also quickly benefit from gains to their self-esteem, if they have had a previous background of marginalisation, and so the experience of expending individual funds is in contrast novel and rewarding.

The ABIOS pilot may have some cultural benefits. Workers reported on outcomes for participants from CALD backgrounds who were able to access non-traditional support and resources which worked very effectively for them. Two participants in interviews who were from CALD backgrounds valued the flexibility of the pilot to meet their particular circumstances.

There is some concern among the ABIOS workers that some people might not be benefiting or are excluded from the pilot. In particular people with acquired brain injury who have acquired the impairment within the last five years (and thus fall within the ABI early intervention criteria), but who are outside the chronological age range for the program, are ineligible for the pilot. ABIOS case managers expressed their frustration that people above the 35 years were excluded although they would be likely to benefit from the program.

Government stakeholders and service providers identified several groups who could benefit as priority groups for the program, including children with disability aged 10 – 15; parents aged over 40 years with acquired brain injury; Aboriginal and Torres Strait Islander people with disability, particularly those

---

in communities with high levels of foetal alcohol syndrome and remote communities. One policy maker said

The limited number of groups and the tight scope meant that a lot of parameters haven't been tested. High end needs, rural and remote, the person's capacity to have the money in their bank account ...

### **Future development of the program**

The program is achieving its process objectives: empowerment of service users and their families to identify their needs, set personal goals and make informed decisions about the support they need.

The pilot, designed as an early intervention approach, is reaching its main target groups – children showing early signs of additional support needs, young adults with physical disability, and their families and informal supports, previously excluded or not accessing more formal support. The analysis has also identified a number of questions about possible limitations and challenges to this model of support, in addition to those raised in the Baseline report.

Some workers and participants are unclear and need guidance about exit processes, such as funding and participation after the first 12 months in the program. In ABIOS, because some young adults are already ABIOS clients, some workers are unsure whether to commence planning and then introduce the SDS pilot, or introduce the pilot first, then start planning with the funding in mind.

Some ABIOS workers thought that to address the young adults' lack of experience with planning and decision making where resources are available, training resources for participants and families to support learning in this area may be helpful, prior to formal planning.

Workers identified the importance of supervision, peer support, interaction with other workers within their agency, and strategies for culturally appropriate ways to engage families from non-English speaking and Indigenous backgrounds.

ABIOS workers said they need further development and training about case management processes to manage risk for young adults' needs, in a new climate where people are encouraged to make a far broader range and scope of personal decisions.

The administrative processes to comply with financial accountability, planning processes and evaluation are a high cost to the organisations.

Opportunities for expanding the program include:

- Avoiding terminology such as 'disability' to include families who do not identify with the category;

- 
- Extending the program beyond physical disability and six years of age, to include children with mental health disorders, learning difficulties, and challenging behaviours, up to ten years of age;
  - For young adults, revising eligibility to length of time since acquiring impairment, rather than chronological age; and
  - Promotional material to explain the program in a way that is attractive and understandable for young adults and families of young children.

SCCTC workers suggested that enhancement of the community development and capacity building aspects of the pilot would be important, for example, by introducing peer-to-peer support groups (eg. playgroups) for children, their families and carers. Such a platform could provide on-going support and community integration for participants, and serve as link for providers to provide information and pathways into support services. Parents new to the program in 2011 have volunteered to coordinate this, as they are aware that the coordinator does not have time.

The views of participants, service providers and policy makers are consistent that the program is meeting the goals of community inclusion and empowerment. The goals are facilitated through strong relationships and support processes implemented by case workers; a partnership approach to planning and decision making where participants need guidance; flexibility in planning, with the option of making changes to plans as circumstances and preferences change; and consistency to the principles of the program design. The financial and administrative arrangements sometimes compromise the effectiveness of these processes (Section 4.3). A government stakeholder said,

The key is definitely the planning – the ability to sit down and plan not only your disability specific needs, but plan a life or your interaction with the community ... That's key, I think. It's starting to grab hold of their life goals, and not their disability support goals.

---

## 5 Economic evaluation

An economic evaluation assesses the cost of the pilot against the outcomes experienced by the participants. These costs are analysed in terms of total program cost and cost per participant. The underlying principle of the economic analysis is that for the given budget, the government wishes to maximise participant benefits. The economic analysis also informs future decisions about the pilot or similar support models for people with disability.

### 5.1 Costs of the program

In this section of the evaluation we analyse cost data provided by the Department and the service providers. The evaluation includes a cost analysis to determine whether the pilot provides value for money, positive outcomes for participants relative to costs and viable service program.

The NGOs are each funded \$240,000 per year for two years to pay for management, operational and case workers time and expenses and small self directed funding packages (\$4,000 per year per person). Funding is equally allocated to participants regardless of their assessed or perceived level of support needs.

It is difficult to estimate actual program costs based on the budget information provided by the services, as the information was not located in one place and many of the costs had not been finalised by the time the data were collected. To make the estimates, costs for services were averaged. As the two groups were very different, the costs for each are presented separately.

Although many costs are unclear, it is apparent through the case notes that case workers work with the young adults and families to provide services that are within budget, and have indicated that if a support service costs more than the budget, then the family contributes to the payment. It would be reasonable to assume therefore that the associated program budget for participant expenditure does not exceed the allocated annual budget.

The range of costs for each support type is presented Table 5.1. These costs are based on 50 participants with costs for 44 identified needs. Of these, 38 children, and 12 young adults had costs listed against at least one of their identified needs. The data are incomplete.

**Table 5.1 Cost details of identified needs January 2010 to May 2011**

	Number participants	Range of costs (\$)	Average number of hours	Average cost per hour (\$)	Average total cost per participant(\$)
<b>Total cost of identified needs</b>					
Children	38	619-4000			2287
Young adults	12	996-4429			3231
<b>Children</b>					
<i>Ongoing or weekly services</i>					
Allied therapy (Physio, speech, OT)	51		6	89	573
Child care	1		-	-	1820
Hydro therapy	1		10	40	400
Horse therapy	1		10	35	350
<i>One-off costs</i>					
Equipment	19				517
Medical treatment	1				747
Other home or family costs	5				866
<i>Needs with no direct cost associated</i>					
Assessment for diagnosis	1				
<b>Young adults</b>					
<i>One-off costs</i>					
Community education course	3				270
Equipment for community education	2				2425
Formal education course	1				559
Equipment for formal education	1				2117
Sports/social fitness program /equipment	4				805
Other household costs	3				1374
Other personal costs/social activities	2				2025
Removal costs	1				2250
<i>Ongoing or weekly services</i>					
Personal trainer	1		5	80	400
Support person	1		16	40	640
Driving lessons	1		10	50	500
Swimming lessons	1		20	17.50	350
<i>Needs with no direct cost associated</i>					
Personal assistance –diet and exercise plan, personal and career goals	3				
Assistance with living with family	1				
Assistance with community involvement	2				

Sources: Program tracking data between 2010 and 2011. Young Adults: program tracking data supplied in May 2011 for a subset of clients in the program.

Notes: The number of participants indicated was used to calculate the cost details, and do not represent all participants who received a service, as data for some participants did not indicate finalised costs for services.

Total costs are provided only for participants who had all needs costed and is not representative of all participants, it may also not be a final cost as some budget was left over for these clients.

A small number of identified needs involved no direct cost (e.g. additional case management, budgeting assistance), these are included for information.

---

The basic cost data shown above indicate that there is wide variation in the cost per service as well as the total cost per participant in the program.

The most immediate finding apparent in the data is the method in which the allocated budgets are spent. For the young children, the budget is generally allocated to a service that is delivered over a number of weeks (usually six) and then reviewed. The costs above only include one round of services. Equipment is then purchased from the budget and then if there is any remaining money, it is used on other expenses.

This pattern of funding allocation for the young children appears to be because most families prioritised therapeutic assistance before other needs could be met, and for these participants this is delivered in weekly sessions. Only a small number of participants in the younger group prioritised a need that required a one-off cost.

The young adults tended to prioritise their spending on one-off items. Usually this was some kind of equipment to assist them with formal or community study. They appeared to allocate money to the need with the most impact in terms of community and social involvement and personal wellbeing. This meant that the young adults spent their budget early on in their participation in the program with the intention that they will use the item/s they purchased to participate in the community over a long period of time.

An example that illustrates the typical difference between the spending patterns of the two groups would be physiotherapy for a young child compared to a young adult purchasing clothing, shoes and purchasing a gym membership. For the child, the services coordinator booked in six weeks of physio to be reviewed upon completion. The physiotherapist recommended that the family purchase some equipment and then with the remaining money was spent on a family activity. The young adult on the other hand decided that they would prioritise their fitness and get out of the house more. They decided that they would join a gym, so they required the money to buy clothes and shoes and a gym membership.

It can be assumed that for the adults this one-off expenditure followed by community participation would not incur any major cost outlays after the initial expenditure. For the young group, however, there may be situations where additional therapy is required and if the budget is already spent, the family cannot afford to pay, and free or subsidised support is not available, it might affect access to continued treatment. tables.

## **5.2 Benefits of the program**

The results in Section 3 demonstrate benefits the participants experienced as a result of the pilot, including changes in participants' wellbeing (satisfaction with personal relationships, health, self reliance); social, community and economic participation; and community connections, summarised in Table 5.2.

---

**Table 5.2 Summary of Self Directed Support outcomes**

Outcome	Description
Wellbeing, independence and resilience	<p>Participants' physical wellbeing has improved from access to therapies and physical activity. This has improved their independence.</p> <p>Family members wellbeing and resilience to cope with their circumstances has improved through reduced stress about coping with decisions about support needs, paying for support, finding information and arranging support.</p> <p>The wellbeing of young adults and family members is close to that of the Australian population and higher than other carers.</p> <p>Families report that the support is preventing them from entering a crisis and perhaps avoiding family breakdown.</p>
Empowerment	<p>Young adults have been able to make decisions and act on plans to achieve steps towards goals</p> <p>Family members have a better sense of control and capacity to organise, pay for and attend support services for their children.</p>
Social, community and economic participation	<p>Young children are able to participate in activities in their family, early childhood groups and school.</p> <p>Young adults are participating in sport, social and educational activities and paid employment.</p> <p>Support has enabled families and siblings to do activities together and outside the home.</p>
Community connections and networks	<p>Young adults are accessing mainstream services.</p> <p>Families of young children are becoming familiar with community services and referral opportunities.</p>

### 5.3 Economic implications for program and evaluation

The providers have operated within budget for the first 18 months of the program. They reported that they have absorbed a lot of management costs into their other operations because of the high administrative responsibilities of establishing a new program. The self directed funding allocation has also operated within budget. The families of young children have generally spent the funds on weekly fees for therapies and related equipment. The young adults in contrast have paid for equipment or study fees to facilitate immediate access to social, community and economic activity.

The qualitative data shows that young children, their families and young adults are benefiting from case management, planning and a small budget to assist with organising the support they need to fulfil their goals. Benefits for

---

the participants and their families are evident including wellbeing, independence and resilience; and community, social and economic participation. Initial information and contact with community services and informal networks is beginning for some families and young adults, but with the support of the case workers, this benefit is taking longer to experience than the others.

---

## **Appendix A Evaluation Methodology**

A longitudinal, mixed method evaluation design is used to measure longitudinal outcomes for children and young adults with physical disabilities, their families and informal supports; the program process; and costs of the pilot. The methodological approach has been developed to fit the attributes of the Self Directed Support pilot, the evaluation objectives and the conceptual framework outlined. It is designed within the evaluation constraints such as available and prospective sources of information, budget, timeframe and respondent burden.

The evaluation aims to generate information about the Self Directed Support pilot throughout the evaluation period to inform progressive policy and program change. Key areas of the evaluation include outcomes and process evaluation; and an economic analysis that compares the costs of the pilot to the outcomes for people with disabilities and their families and informal support.

This is a summary of the more comprehensive evaluation plan of the Self Directed Support Pilot (Gendera et al. 2010). (Also available under [www.sprc.unsw.edu.au/media/File/3\\_SDS\\_Evaluation\\_Plan.pdf](http://www.sprc.unsw.edu.au/media/File/3_SDS_Evaluation_Plan.pdf))

### **Evaluation questions**

The evaluation of the Self Directed Support pilot addresses three sets of research questions:

1. Participant and program outcomes: To what extent has the initiative met its objectives for individual participants?
2. Support model and service delivery processes: How effective is the model in meeting its key objectives, person centred (self directed) support, community inclusion, and early intervention?
3. Economic analysis: What are the costs and benefits of the pilot?

### **Data sources**

In summary the data sources used to answer the evaluation questions include:

- Document review – policy, documents and literature;
- Administrative and program data – Department specifications, service contracts, financial data and case planning data;
- Qualitative data collected by the evaluation team – case studies, interviews and observation data; and
- Quantitative reporting from the service providers – quarterly and annual reporting, assessment data and validated Personal Wellbeing Index questionnaires.

---

The evaluation is conducted in four phases: project plan; baseline analysis; longitudinal analysis; and final analysis. As of November 2010 the evaluation plan has been completed and published.

## **Methodology**

The evaluation uses quantitative and qualitative data and incorporates a participatory methodology. The participatory research design acknowledges that the success of the evaluation strongly relies on the meaningful participation of a range of stakeholders throughout the research process.

### *Quantitative data*

The main sources of quantitative data for this evaluation are provided by the Department respectively the two selected NGO service provider agencies, SCCTS and ABIOS, as part of their quarterly and annual reporting on participants' demographics, case planning, service types, and financial reporting.

The two sources of information are: extracts from the National Minimum Dataset (MDS) which includes basic demographic information and the number of case management hours provided to pilot participants; and program data which tracks participants' identified needs and support types used. The information on processes and outcomes provided in this baseline report capture the early stages of the pilot implementation. Longitudinal data analysis will allow the evaluation to measure change over time.

To assess the outcomes for all adult respondents – the young adults, their informal supporters and the informal supporters of the children participating in the pilot (one informal supporter per participant) – the evaluation is collecting data from the Personal Wellbeing Index (PWI). The two service provider agencies have agreed to collect and transfer the PWI data for the adult pilot participants. By November 2010 this process had not yet commenced. The rationale behind this choice of validated instrument is that it contains specific questions on personal wellbeing as well as information on seven life domains that can be used as indicators for assessing resilience, e.g. health, material comfort, work engagement and community participation, which are the core objectives of the pilot program. In addition, the PWI is a validated instrument which uses reliable Australian scales which are short and therefore relatively quick to administer.

The evaluation framework was designed to assess outcomes for children and young adults participating in the pilot by analysing supplementary outcome data, in form of standardized measures collected by service providers. However it became clear that no strengths-based validated instruments are available to assess outcomes especially for young children and their carers. After careful consideration of the possible negative impacts on families the researchers in consultation with the Department decided not to collect any supplementary data (apart from the PWI for the adult population).

---

### *Qualitative data*

Researchers are conducting semi-structured interviews with pilot participants, their informal supports, service providers and Department staff about the outcomes and process elements of the evaluation.

The total qualitative sample includes at least ten pilot participants, 14 informal supporters, six service provider staff and two managers in both regions and three Department officials (Table A.3). The sample size is the minimum recommended to meet the evaluation requirements within the constraints of the budget and respondent burden. It is large enough for case study data to supplement the full cohort continuous longitudinal quantitative data. Baseline qualitative data are being collected from September to December 2010, and longitudinal data will be collected in September 2011.

**Table A.3 Longitudinal qualitative interviews September 2010 and 2011**

	2010 baseline report		2011 second report		
	Children 0-6 years	Young adults 20-35 years	Children 0-6 years	Young adults 20-35 years	Others
Pilot participants	-	10	-	10**	-
Informal support eg. family	10	3	9**	4	-
Service provider staff	1	8*	1	1	-
Service provider manager	1	1	-	-	-
Department staff	-	-	-	-	3

Note: The qualitative samples supplement the full participant population quantitative datasets  
\* Three interviews with eight ABIOS staff.  
\*\*longitudinal (repeat) interviews were conducted with five of the 10 ABIOS participants; and four of the nine family members of children participants.

We do not recommend representative sampling because the quantitative data collection includes all participants who permit their data to be analysed in a deidentified form and the qualitative case study sampling is only large enough to include at least one person with each diverse characteristic rather than a representative number, which would risk excluding people with less frequent characteristics.

To avoid selection bias and maximise the longitudinal research opportunities, the samples are selected on the basis of the last pilot participants and their informal supporters who meet the final sampling framework criteria, who entered the pilot before the evaluation began and agree to participate.

The evaluation also uses qualitative program data about participants who permit the analysis of their deidentified data. This data includes information collected by case workers throughout the planning and goal setting stage and later ongoing support provision (eg. case planning notes).

### *Program observation*

While conducting interviews with key stakeholders, managers and service providers of the two NGO's, the research team spends time in each of the two fieldwork sites (Brisbane and Sunshine Coast) to explore how the program operates in specific contexts. These data are used to further inform the

---

outcomes of the pilot. ABIOS is also collecting evaluation data, using a tool their research officer has developed for the purpose.

*Economic evaluation*

The evaluation includes a cost analysis to determine whether the pilot provides value for money, positive outcomes for participants relative to costs and viable service program. The evaluators analyse financial budget and expenditure data provided by the Department and service providers in their quarterly financial and annual reports to examine the costs of the program (including management, establishment, brokerage and administration and participant service costs).

Program costs are compared to the outcomes. The aim is to compare the goals of the program with its achievements, deciding whether the program is economical in terms of tangible benefits produced by money spent. This will help to understand how effectively the government has achieved its objectives. This component of the evaluation heavily relies on outcome and cost data being available and is likely to be stronger in the longitudinal analysis (round two reporting).
